Comp 388/441 - Human-Computer Interface Design

Week 4 - 11th February 2016

Dr Nick Hayward

- context in user interaction is important
 - helps establish an application in a user's short-term memory
- predominant models for human memory include
 - short-term or working memory
 - long-term memory
- inter-related structural nature of working and long-term memory

Short-term, working memory

- conceptually similar to a temporary memory store
- able to hold a limited amount of data
 - might include words, numbers, symbols...
 - related to current user task
- working memory decays quickly & often lost
 - we lose focus, switch to another task...
- rehearsal and repetition of a given task is useful prevention
 - helps us maintain useful or important information
- capacity of working memory
 - "seven, plus or minus two"
 - Miller, G. A. "The magical number seven, plus or minus two: Some limits on our capacity for processing information." 1956.
- 7 numbers for North American local dialling
- harder for most people to hold more than about 7 digits...

Changing limited capacity in working memory

- free up working memory to replay and rehearse new information
- compare with computer memory, and related performance without free memory
- learning is naturally reduced and slows down
- a good example of this is mental arithmetic
- difficult to hold even limited amounts of information and process effectively
- burden on working memory is known as 'cognitive load'
- reduction of cognitive load fosters learning by freeing working memory

Long-term memory

- more permanent, persistent store
- allows us to save and recall knowledge, memories at a later date
- store any facts, both good and bad
- also stores procedures and skills
 - both cognitive and sensory-motor tasks related
- also permanent memory store
 - some data will naturally degrade or deteriorate over time
- may experience some sense of false recall
 - memory items become confused or combined irregularly

The very act of memorisation

- the act of intentionally committing something from short-term to long-term memory
- normally achieved through repetition
 - more frequent we encounter something, more likely we are to remember
- eg: studying involves actively & intentionally re-reading, rehearsing & practicing
- also need to be able to store other long-term data
 - important, novel, surprising, and unusual information without repetition
- exact nature of how this works still remains largely unknown
- such memories are believed to be stored symbolically
- we may not retain exact copy of event or material
 - instead we create symbolic hooks to allow easier recall of data

Memory storage & recall

- tend to store information in logical groupings
- psychologists refer to this as chunks
- memory most effective when **chunks** are related
 - these are logical connections or relationships
- eg: association between a person and related information
 - their face and name
 - their job title and name
 - family or colleague associations...

Memory recognition & recall

- recall of information, events etc normally triggered by a prompt or cue
 - eg: recognising someone in a crowd may trigger recall of their name...
- more recent information tends to lead to better recall
 - known as **recency effect**
- often easier to recall related information as well
- poor, fractured recall shows imperfect nature of long-term memory
- often recall hazy or false data from long-term memory

Retrieval and transfer of new knowledge and skills

- not sufficient to simply add new knowledge to long-term memory
 - new knowledge needs to be easily retrieved in context
- retrieval of new skills essential for successful transfer of knowledge and experience
- interface design necessarily needs to incorporate context to help retrieval
 - examples and practice exercises
 - simple mnemonics as a child
- job learning and training scenarios, role play, troubleshooting exercises...
- link or hook new knowledge to long-term memory

Human Memory - Improving Memory Video

Our brain forgets...

- less frequently accessed chunks of information or skill processes
 - more likely to be forgotten
 - natural aspect of our brain's memory structure
- recency effect tends to protect daily routines...
- older facts more easily become hazy or unclear
- loss of long-term information is not universal
- highly developed motor & cognitive skills with sense of easy repetition
- some things are simply like riding a bike
