Comp 341/441 - HCI

Spring Semester 2018 - Week 2

Dr Nick Hayward

Perception

- colour perception in humans
  - *inherent strengths and weaknesses*

- a few limitations in everyday lives

- considerations as UI designers
  - *presentation of colours affects a user's ability to recognise and distinguish them*
  - *display influences a user's perception of colour*
    - eg: their monitor, screen or other viewing device
  - *user's vision optimal at detecting contrasts, edges*
    - not absolute brightness
  - *some users may have some degree of colour-blindness*

A comparison of glare (source: Amazon)

The lowest reflectance of any tablet.

iPad Air 2 features a custom-designed antireflective coating that reduces glare by 56 percent, making it the least reflective tablet in the world. In virtually any kind of environment — offices, classrooms, outdoors — everything is clearer and more readable.
Reducing glare - Apple iPad Air 2 (source: Apple)

Rods and Cones

- retina at the back of the eye is used for focusing images
- retina has two types of light receptor cells
  - *known as rods and cones*
- *rods* detect light levels, but not colours
- *cones* detect colours
  - *three types sensitive to red, green, and blue light*
 - *often compared to video cameras, monitors...*

Human Eye

The Human Eye (source: DoveMed)
Modern Environmental Influences

- we need to consider the effect of environmental conditions on human vision
  - *modern working and living spaces*

- rods are sensitive to the environment's overall brightness

- three types of cones sensitive to different frequencies of light

- bright artificial lights dramatically reduce the use of rods
  - *rods designed for low levels of light*
  - *navigating low-light environments*

- bright artificial lights max out our rods
  - *rods provide no real useful information*

- vision becomes reliant on input from cones

Visible Light Spectrum

Visible Light Spectrum (source: Wikimedia)

- S-cone = short-wavelength sensitivity
  - *sensitive to light over almost the entire range of visible light*
  - *most sensitive to the middle (yellow...) and low (red...) frequencies*

- M-cone = middle-wavelength sensitivity
  - *less sensitive than S-cones*
  - *sensitive to light ranging from high-frequency (blues...) through middle frequency (yellows & oranges...)*

- L-cone = long-wavelength sensitivity
  - *less sensitive than either S or M-cones*
  - *most sensitive to upper end of visible light spectrum (violets through blues...)*
  - *our eyes are less sensitive to violets through blues than other colours*

Combinations in the brain

- our brain works on the principle of subtraction
- visual cortex at the back of our brain does the work
  - *neurons subtract signals coming along the optic nerves from S and M-cones*
  - *produces red-green difference signal channel*
  - *neurons subtract signals from L and S-cones*
  - *produces yellow-blue difference signal channel*
  - *third set of neurons as the signals from S and M-cones*
  - *produces an overall black-white, or luminance, channel*
- three channels known as *colour-opponent* channels

Vision & Contrast - 1

Sensitivity

- our vision is now much more sensitive to differences in colour and brightness
  - *greater sensitivity to contrasting colours and edges*
  - *less sensitivity to absolute brightness levels*

- greater sensitivity to contrast is an advantage
  - *more easily discern objects in varied light*

- sensitivity to colour contrasts rather than absolute colours
  - *allows us to discern colour of an object in bright light or shade*

Grey Square Optical Illusion - Source: YouTube

Shade and Shadow

- on the 2D plane
  - *we often struggle to understand why the two colours are the same*

- importance and effect of shade
  - *its effect on the brain's perception of colour*

- our brain is compensating
  - *for the shadow &*
  - *adjusting the colour of square B*

- our eyes see the squares as the same grey colour

- our brain adapts perception
  - *to match what we think is actually the real representation*
 - *i.e. real representation of colours and square B*

Colour presentation

Colour blocks

Colour Presentation (source: National Geographic - Modified)

Presentation factors

- **colour patch size**
  - *harder to discern colour as objects get smaller or thinner*
  - *text is a good example of thin rendering*
  - *text colour is often hard to discern - e.g. black and navy...*

- **paleness**
  - *as colours become more pale, it's harder to differentiate similar tones*

- **separation**
  - *as colour blocks become more separated*
  - *harder to determine their colours*
  - *particularly true with eye motion from one colour block to another*

a few suggestions

A few things to avoid in images & graphics

- try to avoid overly pale colours
- avoid pale colours juxtaposed
- avoid pale colours for smaller blocks or zones
  - *often simply lost in the noise of larger zones and blocks*
- carefully consider chosen colours for charts, graphs, infographics...

Vision issues - 1

colour blindness

- does not infer an inability to see colours
  - *a defect with one or more colour subtraction channel*

- makes it difficult to distinguish certain pairs of colours
- most common form of colour blindness is lack of red-green perception
- ~8% of men & ~0.5% of women suffer
  - *source: Wolfmaier, 1999*

human colour perception

Key

- left = normal human colour vision
- right = human Red-Green colour blindness

Vision issues - 4

colour differentiation & impact

- consider data visualisation
  - *we may use colour to differentiate quantity, scale, percentages...*

- for a person with red-green colour blindness
  - *impacts their ability to discern such data differentiation solely based upon colour*

- we may rectify this issue in at least two respects
  - *modify our colours to match those perceived by red-green colour blindness*
  - *offer supporting data and explanation for the visualisation*

- not always possible to create a full data visualisation for colour blindness
  - *e.g. one that easily differentiates such quantities and values*
  - *due to limited palette for red-green colour blindness*

colour differentiation

Colour Difference - Red/Green Blindness
Colour perception (source: Okabe, M & Ito, K. 2008)

Other issues to consider...

- ambient lighting has a direct impact upon a user's display
  - *washed out, distorted colours*
  - *light and dark areas may persist*
  - *mobile & wearable considerations*

- display viewing angle affects a user's interpretation of colour
  - *cheaper, non-IPS displays offer poor viewing angles and colour shifting*

- mono or greyscale displays directly influence design choices

- variation in colour across competing display technologies
  - *deeper blacks, richer colours, varied viewing angles*

The Bible with Sources Revealed - Source: Amazon

Colour suggestions

Colours - Red/Green Blindness

- subtle colour differences versus saturation, brightness, and hue
  - *test in monochrome to discern zones of coloured differences*

- distinctive colours aid a user's visual system in the combination of colours and visual recognition
  - *black, white, red, green, yellow, and blue*

- try to avoid colour pairs that colour blind people can't distinguish
  - *eg: dark red vs black, dark red vs dark green, blue vs purple, and light green vs white*
  - *try those colours against yellows and greens*

- try adding supporting recognition to colours within your interface
 - *eg: icons, keys, notes...*

Peripheral vision

Peripheral vision - consider spatial resolution in human vision

- spatial resolution drops greatly from the centre to the periphery

- three known reasons for this phenomenon
  - *data compression*
    - information compressed, associated data loss from visual periphery

  - *pixel density*
    - eye has ~ 6-7 million cone cells in the retina
    - cones densely packed in centre of vision, known as **fovea**

  - *processing*
    - fovea is ~ 1% of the retina
    - brain's visual cortex uses ~ 50% of its area for input from the fovea
    - remaining area for other 99%

- vision has much greater resolution in the centre than elsewhere
  - *Waloszek, G. 2005*

foveal resolution
Foveal Image

Foveal Image (source: Illustrated Dictionary of Computer Vision)

Is peripheral vision any use?

Three primary functions for peripheral vision:

- better vision in the dark
- detects motion
- guides the fovea, our centre of vision

Vision & Interfaces

application in user interfaces

- one of the primary issues is a user's focal point relative to other interface elements
- error messages are an example of this issue
  - *user's focal point at button or clicked link...*
  - *messages often missed if presented within peripheral vision relative to link...*
  - *messages need to be obvious relative to focal point of fovea*
- other design considerations for peripheral vision
  - *standard design options*
  - *colour, font or icon size, relative positioning, opacity...*

Vision & Interfaces

make messages visible...

- use a user's focal point to our advantage as designers
  - *put the message at the focal point*

- user's tend to focus in a predictable manner with user interface interaction

- inherent predictability can be used to guide design
  - *western users tend to follow a pattern of movement for forms, panels &c.*
  - *top left to bottom right*
  - *click a link and obtain focal point*

- mark an error prominently to help users
  - *normally place the message near the source of the error*
  - *or relocate to focal point if discrepancy in the user interface*

make messages visible...cont'd

- consider adding an error icon or symbol to the message output
  - *ensure icon or symbol is consistent throughout application, website...*

- reserve a single colour for error messages throughout the interface
  - *customarily red colour used for error and danger messages*
  - *consider red colour relative to company or brand image*
  - *red considered good luck, auspicious in Chinese culture*
    - often associated with death in Egypt...
  - *if necessary, change colour and add error icon &c. to help reinforce different colour*

Vision & Interfaces

overt interface options

There are also more obvious options for attracting a user's attention.

- a message in an error dialog or modal box
  - *gets attention quickly and forces a user to interact before continuing*
  - *use with caution, can be very annoying if abused*
  - *carefully consider context before deploying modal options*
  - *traditional popups can be overridden in browser settings*

- use sound to reinforce an error message
  - *system beep or warning common tool for notifying users*
  - *notifies a user to check the interface for more information*
  - *consider as a support, reinforcement to visual messages*
  - *again, quickly becomes annoying if abused*
  - *environmental conditions important as well*
  - *vibrations an alternative for mobile apps...*

Vision & Interfaces

overt interface options...cont'd

- animated notifications work with our peripheral vision's motion tracking
  - *peripheral vision's ability to detect motion*
  - *detection causes reflexive eye movement towards the screen*
  - *animations often seen in interface menu selections*
    - menu blinks or flashes to indicate selection of option

Considerations

- these options should be used sparingly in a user interface design

- such visual options are often associated with annoying advertisements

- context is important

- consider advanced options to cancel or limit such interface options
